Function of non sugars in sirup formation P. M. Silin and Z. A. Silina. *Sakharovaya Prom.* 19, No. 6, 22-30 (1940).—The basic formula for calcg. the sirup-forming ability is $m_0 = q_0/(100 - q_0)$, where m_0 is the sirup-forming coeff., and q_0 is the quality index of the sirup (cf. Silin, *Khimicheskii kontrol' svklosukharinoj proizvodstva* 1938, p. 170). To the sirup was added a quantity (α) of a nonsugar, e.g. NaCl. On this mixt. were detd. q_1 analogous to q_0 and m_1 analogous to m_0 . The sirup-forming coeff. (m_1) of the added substance was calcld. from the equation $m_1 = m_0 + 100/\alpha.(m_1 - m_0)$. The coeff. m_1 for various substances was detd. It ranges from 0.10 for invert sugar to 4.01 for NaOH. Some of the Ca salts tested had neg. m_1 . The cations tested had different m_1 values, but for any one cation m_1 was detd. by its anion. In decreasing order of m_1 the tested cations were K > N > Ca. The decreasing order for the tested anions was OH⁻, CO₃²⁻, CH₃COO⁻, Cl⁻, glutamate, tyrosine, lactate, decompn. products of invert sugar, and NO₃⁻. The nonsugars can be divided into 3 groups: (1) strong sirup formers ($m_1 > 2.1$) comprising alkali metal hydroxides, carbonates, acetates, and chlorides; (2) medium sirup formers ($m_1 = 1.1-0.8$) including betaine, K and Na salts of amino acids and lactic acid; and (3) weak sirup formers (m_1 less than 0.8) comprg. invert sugar and salts of its decompn. products, Ca salts and NaNO₃.

TITLE: Synthesis and investigation of cross-linked polyarylates

SOURCE: Khimicheskiye volokna, no. 1, 1965, 35-38

TOPIC TAGS: polyester, stress measurement, strain measurement, solubility, thermal stability, polymer, formaldehyde/ Novolak No. 18

ABSTRACT: The authors' purpose was a study of the possibility of increasing heat resistance of known polyarylates by partial cross-linking of their polymer chains. In this study polyarylate of phenophthalein and isophthalic acid and a mixed polyarylate of n,n'-dioxydiphenylpropane, terephthalic acid, and isophthalic acid (in the proportions of 1:0.5:0.5 mole) were used. For cross-linking agents the authors used Novolak No. 18 and formaldehyde. Examinations were made of infrared absorption spectra, x-ray powder photographs, solubility, strength, and elongation. The study indicates that cross-linking of linear polyarylates may be effected with Novolak and formaldehyde. The degree of cross-linking depends on the amount of cross-linking agent, the temperature, and the duration of the reaction. Films of cross-linked polyarylates are insoluble in organic solvents, and they possess high thermal stability. "In conclusion, the authors express their thanks to B. L.

TITLE: Heat resistant films from thermoreactive polyarylates

SOURCE: Khimicheskiye volokna, no. 3, 1965, 16-19

TOPIC TAGS: heat resistance, organic synthesis, polycondensation, mechanical property, strengthening

ABSTRACT: The authors previously studied a number of polyarylates and the effect of structuration on their heat resistance. In the present study of polyarylates from phenophthalein, an attempt was made to introduce into the chain a small number of radicals of a compound containing double bonds, to study the properties of the resulting polyarylates, and to investigate the possibility of preparing films of high heat resistance from these. Initial materials for the synthesis were isophthaloyl chloride, phenophthalein, and 4,4'-dioxy-3,3'-diallyldiphenyl-2,2'-propane (= diallyldian). The polyarylates were obtained by polycondensation in chlorinated biphenyl at high temperatures (up to 250°C). Polyarylates containing various quantities of diallyldian show almost no difference in strength

Card 1/2

L 57055-65

ACCESSION NR: AP5013980

properties, but with increase in content of diallyldian radicals in the chain the deformability of the films at high temperatures increases. Change in composition of the polyarylate affects the strength properties, the best strength properties being obtained from a combination with the ratio of isophthaloyl chloride : phenophthalein : diallyldian = 1 : 0.950 : 0.50. It was found that films of the studied polyarylates may be strengthened at high temperature with and without initiator and also by copolymerization with various vinyl monomers. Films of these strengthened polyarylates have high heat resistance. "In conclusion, the authors consider it their duty to express their thanks to G. L. Slonimskiy for consultations on the physical and mechanical properties of the films and to Ye. N. Prilezhayeva, G. S. Kolesnikov, T. A. Sakharova, and T. A. Soboleva for preparing the vinyl monomers used as cross-linking agents." Orig. art. has: 2 figures and 5 tables.

AUTHOR: Korshak, V. V.; Vinogradova, S. V.; Siling, S. A.

TITLE: Cross linking of polyarylates which contain free hydroxyl groups in the backbone

SOURCE: Vysokomolekulyarnyye soyedineniya, v. 7, no. 4, 1965, 701-706

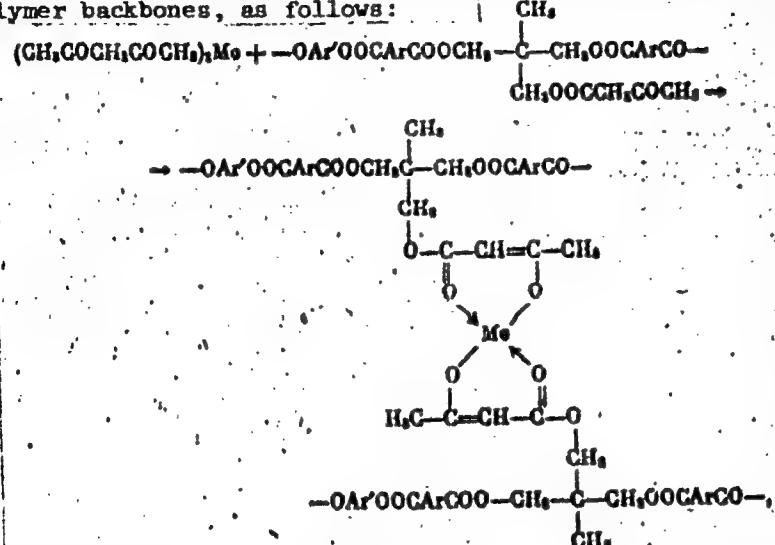

TOPIC TAGS: polyarylate, arylc polyester, cross link, cross linked polymer,
cross linked polyarylate, cross linking agent, metal chelate, metal polychelate,
improved mechanical property

ABSTRACT: The thermal stability and mechanical properties of polyarylates (i.e., arylc polyesters) have been improved, and decreased solubility in organic solvents has been achieved by cross-linking the backbones of polyarylates by a controlled incidence of cross-linking. This controlled incidence is essential for avoiding brittleness of the end product, which is intended for preparing films or fibers. To achieve cross-linking of a thermoplastic polyarylate, the latter was modified by introducing a small number of free hydroxyls as substituents into its structure. Thus, the experiments were conducted with a polymer prepared from phenolphthalein (0.9—0.95 mol), 1,1,1-trimethylethane (0.1—0.05 mol) and isophthalyl dichloride (1 mol). Cross-linking was achieved by the following three
Card 1/17

344162-65

ACCESSION NR: AP5011252

methods: 1) esterifying the hydroxyls with acetoacetyl radicals and subsequent reacting of the organic ligand formed with 5% chloroform solutions of Zn, Cu, Ni, or Be acetonylacetate or Cd acetate, in order to produce metal chelate bridges between the polymer backbones, as follows: CH_3

Card 24

L 44162-65

ACCESSION NR: AP5011252

2

2) esterifying the free hydroxyl groups with anhydrides of dibasic aromatic acids, such as phthalic, maleic, or pyromellitic acid; 3) heating the hydroxyl-containing polymers without any cross-linking agent. The results (tabulated in the original) indicated that, in general, mechanical properties improve after controlled cross-linking, and that the nature of the cross-linking agent has little effect on this improvement. An increase in the amount of the cross-linking agent results in deterioration of the mechanical properties of the films investigated. Direct cross-linking by heating produced somewhat better results than the use of the cross-linking agents. The thermal stability of films cross-linked with a metal decreased in the following sequence of metals used: Cd, Cu, Be, Ni, Zn. It is interesting to note that Ni and Zn chelates were formed even at room temperature without heating, which is necessary for the formation of other chelates, and that Ni- or Zn-chelated films displayed the largest stress formations. This comparatively high deformation (20-40% at various temperatures compared with an average deformation of 5-8% for other metals) combined with nonfusibility and low solubility in organic solvents places the Ni and Zn chelates in an advantageous position as compared to films cross-linked by other cross-linking agents. Orig. art. has: 2 formulas, 3 tables, and 1 graph.

TOPIC TAGS: polyaryl plastic, dicarboxylic acid, formaldehyde, thermoplastic material, polymer, plastic, phenol

ABSTRACT: This Author Certificate presents a method for obtaining heat-resisting polyarylates by treating linear saturated thermoplastic polyarylates (based on bis-phenols and dicarboxylic acids) with novolak or formaldehyde. To expand the assortment of heat-resisting materials, polyarylates based on phenolphthalein and dicarboxylic acids are used as linear saturated thermoplastic polyarylates.

Thiocyanate and endemic goiter. Karel Salnik and I. Maršáková (Central Endocrinol. Inst., Prague). *Nature* 167, 528 (1951). - The amt. of thiocyanate in the blood of subjects with normal thyroids, those with slight hyperplasia, medium or large goiters, with evidence of increased vascularization of thyroid gland or with thyrotoxicosis was determined in two districts of Czechoslovakia with high incidence of endemic goiter. Values in each individual group were greater in the autumn than in the spring, and there was an obvious relation between hyperplasia of thyroid and its vascularization and activity. The thiocyanate values of serum corresponded to those found in subjects receiving less than 0.1 g. & thiocyanate for over a long period. This dose had no goiter-producing effect. Increase in thiocyanate levels in blood without increase in hyperplasia of the thyroid indicates consumption of a goiter-producing substance in food which leads to increase in the thiocyanate level, probably from fresh produce. Apart from iodine many endemic goiter has other biochemically detectable causes. M.M.

and Lipoproteins. Studies with 4-C¹⁴-Cholesterol."

Prague, Casopis Lekaru Českých, Vol 102, No 8, 22 Feb 63; pp 205-208.

Abstract [English summary modified]: Study in 31 rabbits: 13 controls on normal diet, 9 on 1 Qr. dietary cholesterol/day for 6 months, tested 1 month later, 9 same treatment, tested 9½ months later. Cholesterolemia and phospholipidemia in latter group were back to normal, aortic cholesterol was less than in second group, and there was a marked shift of labeled cholesterol from beta- to alpha lipoproteins as compared to first group. Seven tables, 2 Soviet, 1 Czech and 24 Western references.

"Radiation Thyroiditis as a Complication of Treatment with Radioactive Iodine."

Prague, Casopis Lekaru Ceskych, Vol 105, No 19, 13 May. 66, pp 511 - 514

Abstract [Authors' English summary modified]: 321 patients were treated with 357 doses of radioactive iodine during treatment of hyperthyroidism or cancer of the gland. Radiation thyroiditis developed in 44.7% of patients with hyperthyroidism and in 71.3% of those with cancer. The frequency increases in proportion to the dose; it usually appears on the 3rd to 5th day after application of radioactive iodine and lasts for 10 days. Its duration is not influenced by corticosteroids. It differs from perithyroidal edema which developed in the first 48 hours after the iodine was administered. 3 Figures, 11 Western, 5 Czech references. (Manuscript received June 65).

"Relationship Between Carbohydrate and Lipid Metabolism in Patients with Hypercortisolism -- Cushing's Syndrome."

Prague, Casopis Lekaru Ceskych, Vol 105, No 41, 12 Oct 66, pp 1110 - 1116

Abstract [Author's English summary modified]: In 20 patients raised serum levels of non-esterified fatty acids (NEFA), cholesterol, neutral fat, blood sugar level, cholesterol/phospholipid index were found. A correlation between blood sugar level while fasting and the cholesterol blood level was determined. After glucose administration the rate constant of removal of NEFA in serum of patients was lowered, which indicates a deteriorated glucose utilization in adipose tissue hypercortisolism. The reduction in the content of cholesterol and phospholipids after glucose administration is discussed; the role of pituitary-adrenal system in atherosclerosis is described. 3 Figures, 3 Tables, 37 Western, 7 Czech references. (Manuscript received Oct 65).

1773. *Stratigraphical diagnosis of hypophyseal adenomas* Stratigraphische Diagnostik der Hypophysenadenome. SUŠINKOVÁ-MÁLKOVÁ E. and BLAZEK O. III. Med. Klin., Karls-Univ., Prag Endokrinologie 1957, 34:1-2 (2-11)

A technique of extensive stratigraphical examination of the sella turcica, which is cheap, simple and convenient to the patient, is described. This technique ensures a correct spatial image in normal and also in pathological conditions and has proved efficacious especially for the diagnosis of the removal of hypophyseal tumours. The objective picture of all the sellar changes permits an early diagnosis. Comparative stratigraphy in the further pathological course facilitates the judgement of the dynamics of the process. The clinical characteristics and the typical X-ray findings obtained by stratigraphy in 56 cases of hypophyseal adenoma are presented.

EXCERPTA MEDICA Sec 6 Vol 13/2 Internal Med. Feb 59

III. SKELETAL CHANGES IN PITUITARY ADENOMA - Změny skeletu y hypofyzárních adenomů - Šilinková - Maiková E., and Blažek O.
III, Int. Klin., Karlovy Univ., Praha - ČAS. LÉK. ČES. 1957, 96/42 (1334-1342) Tables 8 Illus. 3

In 72 patients with pituitary adenomata - 37 with acromegaly and 35 hormonally inactive - skeletal changes were evaluated by X-ray. By stratigraphy it was shown that in the majority the sella was asymmetrically enlarged, sometimes unilaterally. Characteristic for acromegaly is a thickening of the external lamina in the superior part of the frontalis. Half the males and all the females had calvarial hyperostosis, mainly of a nodular type and severe in degree. The sella may be loculated from excavations in the floor; the tuberculum is often prominent, while destruction of the dorsum is relatively slight. In 2/3 of the cases there are typical spongy appositions on the vertebral bodies. Thoracic kyphosis and lumbar lordosis may be more

marked, a deforming spondylosis more frequent and severe, similar to osteoclastic changes in the pelvis. Average finding at a young age is a deforming arthrosis; the articular space remains wide, however. Long bones are thickened, the region of the joint being thin and coarse, often with a cystic appearance in women. Females on the average have thicker compact bone layers, with thinner diaphyses of the phalanges of the foot. There is a characteristic type of female pelvis with widened hip sockets and a narrowed ramus of the pubis. Acromegaly conditions the growth not only of cartilage and connective tissue, but of bony stroma as well, not interfering with the mineralization of bone. The more marked features of the X-ray picture in women may be explained by the action of oestrogens. Chromophobe adenoma gave no characteristic skeletal changes. The sella may be more rounded, with more marked pressure changes on the dorsum. The more frequent diffuse osteoporosis is probably a result of the decreased production of steroids, and perhaps of growth hormone, in hypopituitarism.

Promulgation: This book is intended for scientists and researchers in the field of spectroscopy, as well as for technical personnel using spectrum analysis in various industries.

Content: This volume contains 177 scientific and technical studies of atomic spectroscopy presented at the 10th All-Union Conference on Spectroscopy in 1956. The studies were carried out by members of scientific and technical institutes and individual creative bibliographies of Soviet and other sources. The studies cover many phases of spectroscopy: spectra of rare earths, electron paramagnetic resonance, methods for controlling electric-magnetic induction, physicochemical methods for controlling arc-welding, production, physics and technology of rare earths, spark spectroscopy, abnormal dispersion in metal vapors, optics and spectroscopy, and the combustion theory, spectrum analysis of minerals, photographic methods for quantitative spectrum analysis of metals and alloys, spectral determination of the hydrogen content of metals by means of isotopes, tables, and atlases of spectral lines, spark spectrographic analysis, statistical study of variation in the parameters of calibration curves, determination of traces of metals, spectrum analysis in metallurgy, thermochimistry in metallurgy, and principles and practice of spectrochemical analysis.

TITLE: An Investigation on the Effect of Polarity of a Sample During the Excitation of Spectrum in an Alternating Current Arc

PERIODICAL: Inzhenerno-fizicheskiy zhurnal, 1959, Nr 6, pp 91-95 (USSR)

ABSTRACT: A standard generator of the PS-39 type and a unipolar arc, the circuit of which is shown in Figure 1, was used by the authors for studying the effect of polarity of a sample on changes in its spectrum and for investigating the processes occurring in electrodes. The following alloys were used for electrodes: carbon steel, medium-alloyed steel, non-rusting steel, brass, babbitt, and the metals: bismuth, lead, tin, cadmium, zinc, aluminum, magnesium, iron, nickel and copper. The measurements have shown that absolute intensity of spectral lines of elements is usually higher at the negative polarity of a sample (cathode conditions) than at the positive polarity (anode conditions), and in particular by a factor of 1.5 to 2 times for steel, 2 to 3 times for babbitt and 5 to 8 times for brass. The course of graduated graphs is discussed and displacements due to effects of "third components" in the samples

TITLE:

An Investigation of the Polarity of the Sample
in the Excitation of the Spectrum in the Alternating-current
Arc

PERIODICAL:

Izvestiya Akademii nauk SSSR. Seriya fizicheskaya, 1959,
Vol 23, Nr 9, pp 1074-1077 (USSR)

ABSTRACT:

The experiments described were carried out with unipolar alternating current. Figure 1 shows the wiring scheme of the device, which permits operation with normal alternating current of 100 cycles and unipolar alternating current of 50 cycles. The experiments were carried out on carbon steel, medium-alloy steels, stainless steel, and brass. It was found that the absolute intensity of the spectral lines in the case of negative polarity of the sample exceeds that of positive polarity 1.5 to 2-fold in the case of steel and 5-8-fold in the case of brass. The ratio between the lines of the alloy elements and the intensity of those of the basic material is greater in the case of anode operation than in that of cathode operation. However, it was found that in the case of cathode operation the influence of third alloy elements becomes negligible. Measurement results in the case of alternating

of the Spectrum in the Alternating-current Arc

current operation are normally between those of anode- and cathode operation, and the alternating current effects are considered to be a superposition of anode- and cathode-effects. The error in analysis is given as amounting to 3.4% alternating current, 3.5% for cathode-, and 5.6% for anode operation. It was found that in the case of cathode operation the rule set up by L. N. Filimonov applies to the lighting-up (obzhig) curve (which represents the time-dependence of ΔS), but for anode operation it does not apply for some elements (especially for Cr, Ni, Si). A diagram (Fig 4) shows the dependence of the relative intensity of the spectral lines of Ni and Fe on the amperage for cathode- and anode operation. In the evaporation of elements, besides thermal- and redox-processes, also the electrical processes on the electrodes play an important part. There are 4 figures and 5 Soviet references.
